```

Data Augmentation

A major challenge with high-resolution art is that compressing a massive painting down to standard 224×224 dimensions destroys the high-frequency details (individual brushstrokes, canvas texture, paint thickness).

- The training pipeline resizes images to 512×512 but takes a random 224×224 crop.

- The Benefit: This acts as a "magnifying glass" placed randomly on the canvas. It feeds the model uncompressed, raw textural data while keeping the tensor size small enough that the flattened sequence length doesn't cause the BiLSTM to crash the GPU memory. Combined with horizontal flipping, this prevented the model from memorizing the dataset over 50 epochs.

```

Model 1

Why **ResNet + Bi-LSTM Architecture**: Spatial Textures + Sequential Brushstrokes

Standard image classification tasks (like identifying cats vs. dogs) rely entirely on spatial hierarchies, making pure CNNs the default choice. However, fine art is fundamentally different. An artist's identity is often hidden in the cadence and rhythm of their brushstrokes, not just the objects they paint.

- **ResNet**:

  Acts as the spatial feature extractor. It pulls the high-level semantic information (edges, color palettes, and structural composition) from the canvas.

- **Bi-LSTM Sequence Modeler**:

  By flattening the spatial feature maps and passing them through a Bidirectional LSTM, the network treats the canvas as a sequence. It scans the image to capture the directional flow and repetitive techniques of the artist's hand.

- Empirical Proof:

  This strategy is validated by the training logs. Typically, "Genre" is the easiest task for a CNN, but our model achieved a significantly higher Macro F1 score for Artist (0.545) than for Genre (0.419) and Style (0.433). The BiLSTM successfully learned the unique signatures of individual painters.

Multi-Task Learning (MTL)

Rather than training three isolated models for Artist, Genre, and Style, utilizing a shared ResNet backbone with three distinct linear heads provides a massive regularization benefit.

- **Cross-Task Regularization**:

  The tasks are deeply correlated. Learning the features that define the "Impressionism" style inherently helps the network identify "Claude Monet." The gradients from the Style and Genre losses prevent the Artist head from overfitting to spurious details.

- Computational Efficiency:

  Processing three tasks through a single backbone drastically reduces the memory footprint and inference time, making the pipeline highly scalable.

```
class ResidualBlock(nn.Module):
    # Standard ResNet block
    # Uses skip connections (shortcuts) to allow gradients to flow
easily, preventing the vanishing gradient problem.

```

Why Macro F1 over Standard Accuracy

The WikiArt dataset suffers from severe class imbalance. A few famous artists and styles dominate the dataset, while hundreds of others have very few samples.

- The Metric Choice:

  If the model optimizes for standard Accuracy, it can "cheat" by overwhelmingly guessing the majority classes. By monitoring the Macro F1 Score, the evaluation metric treats the most obscure 19th-century painter with the exact same mathematical weight as Vincent van Gogh.

- Checkpointing:

The model's weights were saved based purely on the highest Average Macro F1 across all three tasks, ensuring the final network is highly generalized across the entire artistic spectrum.

Outliers

Model 2

Why **ConvNeXt + Bi-GRU Architecture**: Spatial Context + High-Efficiency Scanning

Standard image classification tasks rely entirely on spatial hierarchies, making pure CNNs the default choice. However, fine art is fundamentally different. An artist's identity is often hidden in the cadence and rhythm of their brushstrokes and global composition, not just the objects they paint.

- **ConvNeXt-Tiny (Spatial Extractor)**:

  Rather than relying on a dated ResNet backbone, ConvNeXt acts as the spatial "eyes." By utilizing massive 7×7 depthwise convolutions, it extracts rich, hierarchical visual features (edges, color gradients, and structural composition) with the accuracy of a Vision Transformer, providing a mathematically dense feature grid.

- **Bi-GRU (Sequential Scanner)**:

  By mathematically flattening the ConvNeXt feature grid ($7 \times 7 \rightarrow 49$ sequential patches), the network treats the canvas as a sequence. The Bi-GRU scans the painting top-to-bottom and bottom-to-top simultaneously to capture the directional flow of the artist's hand. Swapping traditional LSTMs for GRUs removes heavy cell-state computations, drastically reducing parameter count and training latency while maintaining deep contextual memory.

- Empirical Proof:

  Training logs strongly validate the hybrid sequential approach. By Epoch 14, the model achieved an 0.823 Macro F1 score for Artist classification, significantly outperforming both Genre (0.729) and Style (0.667). Since identifying a specific painter is historically the hardest classification task, this inverted baseline proves the Bi-GRU successfully isolated the unique, sequential brushstroke signatures of individual painters rather than just recognizing obvious subjects.

Multi-Task Learning (MTL) with Joint Optimization

Using a shared ConvNeXt-GRU backbone with three distinct linear classification heads provides major advantages over training isolated models:

- **Cross-Task Regularization**:

  The target attributes are highly correlated. Optimizing the joint loss function forces the network to learn universally useful representations and prevents individual heads from overfitting to spurious details.

  $$L_{total} = L_{artist} + L_{genre} + L_{style}$$

- Computational Efficiency:

  Sharing the heavy spatial (CNN) and sequential (RNN) extraction phases drastically reduces VRAM usage and inference time. This allows the pipeline to process three complex classification tasks simultaneously while remaining highly scalable for production environments.

```

Vision Transformer

Disclaimer:

I know this explicitly breaks the "Convolutional-Recurrent" requirement! The **ConvNeXt+BiGRU (Model 2)** is my official answer for Task 1.

However, I couldn't resist throwing a modern Vision Transformer at the dataset just to establish a SOTA baseline. While CRNNs are excellent for scanning sequential spatial features, the Deep Learning meta has heavily shifted toward global Self-Attention. To test this, I built a multi-task ViTClassifier by stripping the ImageNet head off a pre-trained ViT-B/16 and attaching my three distinct linear heads (Artist, Genre, Style) directly to the [CLS] token.

```python
class VitClassifier(torch.nn.Module):
    def __init__(self,num_artists,num_genres,num_styles):
        super().__init__()

        self.model = torchvision.models.vit_b_16(weights='DEFAULT')
        self.model.heads = torch.nn.Identity()

        self.artist_head = torch.nn.Linear(768, num_artists)
        self.genre_head = torch.nn.Linear(768, num_genres)
        self.style_head = torch.nn.Linear(768, num_styles)

    def forward(self,input):
        features = self.model(input)

        artist_logits = self.artist_head(features)
        genre_logits = self.genre_head(features)
        style_logits = self.style_head(features)

        return artist_logits, genre_logits, style_logits
```

Model init

```python
model = VitClassifier(
    num_artists=len(artist_uniques),
    num_genres=len(genre_uniques),
    num_styles=len(style_uniques)
).to('cuda')

optimizer = torch.optim.Adam(params=model.parameters(),lr=1e-5)

criterion = torch.nn.CrossEntropyLoss()

scheduler = torch.optim.lr_scheduler.ReduceLROnPlateau(optimizer,
mode='max', factor=0.5, patience=2)

dataset =
ArtDataset(merged_df_train,img_path,transform=train_transforms)
dataloader = torch.utils.data.DataLoader(dataset, batch_size=32,
shuffle=True)

val_dataset =
ArtDataset(merged_df_val,img_path,transform=val_transforms)
val_dataloader = torch.utils.data.DataLoader(val_dataset,
batch_size=32, shuffle=True)
```

Training Loop

```python
